# A GENERALIZATION OF WATTS'S THEOREM: RIGHT EXACT FUNCTORS ON MODULE CATEGORIES

A. NYMAN AND S. P. SMITH

ABSTRACT. Watts's Theorem says that a right exact functor  $F : \operatorname{Mod} R \to \operatorname{Mod} S$  that commutes with direct sums is isomorphic to  $-\otimes_R B$  where B is the R-S-bimodule FR. The main result in this paper is the following: if A is a cocomplete category and  $F : \operatorname{Mod} R \to A$  is a right exact functor commuting with direct sums, then F is isomorphic to  $-\otimes_R \mathcal{F}$  where  $\mathcal{F}$  is a suitable R-module in A, i.e., a pair  $(\mathcal{F}, \rho)$  consisting of an object  $\mathcal{F} \in A$  and a ring homomorphism  $\rho : R \to \operatorname{Hom}_A(\mathcal{F}, \mathcal{F})$ . Part of the point is to give meaning to the notation  $-\otimes_R \mathcal{F}$ . That is done in the paper by Artin and Zhang [1] on Abstract Hilbert Schemes. The present paper is a natural extension of some of the ideas in the first part of their paper.

## 1. INTRODUCTION

Let R and S be rings and let  $\mathsf{Mod}R$  and  $\mathsf{Mod}S$  denote the category of right R-modules and right S-modules, respectively. Watts's Theorem, which was proved by Eilenberg [3] and Watts [7] at about the same time, is the following:

**Theorem 1.1.** Suppose  $F : Mod R \to Mod S$  is a right exact functor commuting with direct limits. Then  $F \cong - \otimes_R B$  where B is an R-S-bimodule.

Let B(ModR, ModS) denote the full subcategory of the category of functors from ModR to ModS consisting of right exact functors commuting with direct limits. The next result is a slightly more precise version of Theorem 1.1.

**Theorem 1.2.** The functor  $\Psi : \operatorname{Mod}(R^{\operatorname{op}} \otimes_{\mathbb{Z}} S) \to \operatorname{B}(\operatorname{Mod} R, \operatorname{Mod} S)$  induced by the assignment  $B \mapsto - \otimes_R B$  is an equivalence of categories.

Theorem 1.1 is then just the fact that the functor  $\Psi$  is essentially surjective.

The main result of this paper (Theorem 3.1) is that if ModS is replaced by an arbitrary cocomplete<sup>1</sup> category A, then a version of Theorem 1.2 still holds. One of the obvious hurdles in proving such a theorem is to have a sensible notion of tensor product in this context. We use the tensor product functor that was defined in [6, Thm. 3.7.1] and investigated in detail in [1] (see Section 2.4).

In Proposition 4.2, we specialize our main result to the case that A is the category of quasi-coherent sheaves on a scheme Y. This version of the main result is used

 $<sup>^{1}</sup>$ An additive category is **cocomplete** if it has arbitrary direct sums. This is Grothendieck's condition Ab3.

extensively in [5] to prove a structure theorem for right exact functors between categories of quasi-coherent sheaves on schemes.

#### 2. Preliminaries

Throughout this paper, k is a fixed commutative ring, R is a k-algebra, and  $\gamma: k \to R$  is the homomorphism giving R its k-algebra structure.

2.1. *k*-linearity. Let A be an additive category. We say A is *k*-linear if for all objects X and Y in A,  $\text{Hom}_A(X, Y)$  is a *k*-module and composition of morphisms is *k*-bilinear. Equivalently, A is *k*-linear if there is a ring homomorphism

$$c: k \to \operatorname{End}(\operatorname{id}_{\mathsf{A}})$$

from k to the ring of natural transformations from the identity functor to itself.

The first definition tells us that for each object  $X \in A$  and each  $a \in k$  there is a morphism  $a_X : X \to X$  such that

for all  $a \in k$  and  $f \in \text{Hom}_A(X, Y)$ . The second definition tells us there are natural transformations  $c(a) : \text{id}_A \to \text{id}_A$  for each  $a \in k$ , and therefore associated morphisms  $c(a)_X : X \to X$  for each  $a \in k$  and  $X \in A$ . The connection between the two definitions is that

 $c(a)_X = a_X$ 

for all  $a \in k$  and X in A.

The k-linear structure on  $\mathsf{Mod}R$  is given by

for all  $M \in \mathsf{Mod}R$ ,  $m \in M$ , and  $a \in k$ .

2.2. *k*-linear functors. Let C and A be *k*-linear categories. A functor  $F : C \to A$  is *k*-linear if the natural maps  $\operatorname{Hom}_{\mathsf{C}}(X,Y) \to \operatorname{Hom}_{\mathsf{A}}(FX,FY)$  are *k*-linear for all X and Y in C. Equivalently, F is *k*-linear if F is additive and

$$F(a_Y) = a_{FY}$$

for all  $a \in k$  and  $Y \in \mathsf{Mod}R$ .

We write

$$\mathsf{B}_k(\mathsf{C},\mathsf{A})$$

for the full subcategory of the category of functors  $C \to A$  consisting of k-linear right exact functors that commute with direct limits. We use the letter B to remind us of bimodules.

It is surely well known that an adjoint to a k-linear functor is again k-linear but we provide a proof of this for completeness.

**Proposition 2.1.** Let C and A be k-linear categories. Let  $G : A \to C$  be a functor having a left adjoint F. If G is k-linear so is F.

**Proof.** Let  $X \in \mathsf{C}$ , and let

 $\nu : \operatorname{Hom}_{\mathsf{A}}(FX, FX) \to \operatorname{Hom}_{\mathsf{C}}(X, GFX)$ 

be the adjoint isomorphism. By the functoriality of the adjoint isomorphisms the diagrams

and

$$\begin{array}{ccc} \operatorname{Hom}_{\mathsf{A}}(FX,FX) & & \stackrel{\nu}{\longrightarrow} & \operatorname{Hom}_{\mathsf{C}}(X,GFX) \\ & g \circ - & & & \downarrow \\ g \circ - & & & \downarrow \\ & & & \downarrow \\ \operatorname{Hom}_{\mathsf{A}}(FX,FX) & & \stackrel{\nu}{\longrightarrow} & \operatorname{Hom}_{\mathsf{C}}(X,GFX) \end{array}$$

commute for all X in C, all  $f \in \operatorname{Hom}_{\mathsf{C}}(X, X)$ , and all  $g \in \operatorname{Hom}_{\mathsf{A}}(FX, FX)$ .

Let  $\theta \in \text{Hom}_A(FX, FX)$  be an element in the top left corner of the diagrams. Let  $f = a_X$  and  $g = a_{FX}$ . The commutativity therefore gives

$$\nu(\theta \circ F(a_X)) = \nu(\theta) \circ a_X \quad \text{and} \\ \nu(a_{FX} \circ \theta) = G(a_{FX}) \circ \nu(\theta).$$

But  $\nu(\theta) : X \to GFX$  is a k-linear morphism so  $\nu(\theta) \circ a_X = a_{GFX} \circ \nu(\theta)$ . Since G is k-linear,  $G(a_{FX}) = a_{GFX}$ . Hence

$$\nu(\theta \circ F(a_X)) = a_{GFX} \circ \nu(\theta) = G(a_{FX}) \circ \nu(\theta) = \nu(a_{FX} \circ \theta).$$

But  $\nu$  is an isomorphism so

$$\theta \circ F(a_X) = a_{FX} \circ \theta.$$

Now take  $\theta = \mathrm{id}_{FX}$  to get  $F(a_X) = a_{FX}$ , so showing that F is k-linear.

2.3. The category  $A_R$ . For the remainder of this paper, we let A denote a k-linear cocomplete category.

A left *R*-module in A is a pair  $(\mathcal{F}, \rho)$  where  $\mathcal{F}$  is an object in A and  $\rho : R \to \operatorname{End}_{\mathsf{A}} \mathcal{F}$  is a *k*-algebra homomorphism. Popescu [6, p. 108] calls  $(\mathcal{F}, \rho)$  a left *R*-object of A. Let  $(\mathcal{F}, \rho)$  and  $(\mathcal{G}, \rho')$  be left *R*-modules in A. We define the set of *R*-module maps from  $(\mathcal{F}, \rho)$  to  $(\mathcal{G}, \rho')$  to be

$$\operatorname{Hom}_{R}(\mathcal{F},\mathcal{G}) := \left\{ \alpha \in \operatorname{Hom}_{A}(\mathcal{F},\mathcal{G}) \mid \rho'(r) \circ \alpha = \alpha \circ \rho(r) \text{ for all } r \in R \right\}.$$

Using these *R*-module maps as morphisms we then obtain a category  $A_R$ , the category of left *R*-modules in A.

Suppose  $(\mathcal{F}, \rho) \in A_R$ . If  $\mathcal{G} \in A$ , then  $\operatorname{Hom}_A(\mathcal{F}, \mathcal{G})$  becomes a right *R*-module through the composition map

$$\operatorname{Hom}_{\mathsf{A}}(\mathcal{F},\mathcal{G}) \times \operatorname{Hom}_{\mathsf{A}}(\mathcal{F},\mathcal{F}) \to \operatorname{Hom}_{\mathsf{A}}(\mathcal{F},\mathcal{G}),$$

 ${\rm i.e.},$ 

$$\alpha.r := \alpha \circ \rho(r)$$

for  $\alpha \in \operatorname{Hom}_{\mathsf{A}}(\mathcal{F}, \mathcal{G})$  and  $r \in R$ . This allows us to view  $\operatorname{Hom}_{\mathsf{A}}(\mathcal{F}, -)$  as a functor  $\mathsf{A} \to \mathsf{Mod}R$ .

Let  $\mu_x : R \to R$  be the right *R*-module homomorphism  $\mu_x(r) := xr$ .

**Lemma 2.2.** Suppose  $F \in B_k(ModR, A)$ . Define the ring homomorphism

 $\rho: R \to \operatorname{End}_{\mathsf{A}} FR, \qquad \rho(x) := F(\mu_x).$ 

Then  $(FR, \rho) \in A_R$ .

**Proof.** To prove the lemma it suffices to show that  $\rho$  is a k-algebra homomorphism, i.e., that  $(\rho \circ \gamma)(a) = a_{FR}$  for all  $a \in k$ . But

$$\rho(\gamma(a)) = F(\mu_{\gamma(a)}) = F(a_R) = a_{FR},$$

where the second equality is due to (2-2). Hence the result.

2.4. The functor  $-\otimes_R \mathcal{F}$ . Recall the standing hypothesis that A is cocomplete. Let  $(\mathcal{F}, \rho) \in A_R$ . By [6, p. 108], the functor  $\operatorname{Hom}_A(\mathcal{F}, -) : A \to \operatorname{Mod} R$  has a left adjoint.<sup>2</sup> We fix a left adjoint and denote it by  $-\otimes_R \mathcal{F}$ . By [1, Proposition B3.1],

the functor  $-\otimes_R \mathcal{F}$  is unique up to isomorphism (of functors) such that

•  $R \otimes_R \mathcal{F} \cong \mathcal{F}$ , and

•  $-\otimes_R \mathcal{F}$  is right exact and commutes with direct sums.

Since the functor  $\operatorname{Hom}_{\mathsf{A}}(\mathcal{F}, -)$  is k-linear for all  $\mathcal{F} \in \mathsf{A}$ , Proposition 2.1 implies the following:

**Corollary 2.3.** If  $(\mathcal{F}, \rho) \in A_R$ , then  $- \otimes_R \mathcal{F}$  is k-linear.

3. The generalization of Watts's Theorem

**Theorem 3.1.** The functor

$$\Psi: \mathsf{A}_R \to \mathsf{B}_k(\mathsf{Mod} R, \mathsf{A})$$

induced by the assignment

$$\Psi(\mathcal{F}) = - \otimes_R \mathcal{F},$$

is an equivalence of categories.

3.1. The proof that  $\Psi$  is essentially surjective.

.

**Proposition 3.2.** <sup>3</sup> Let  $F \in B_k(ModR, A)$ . Then  $F \cong -\otimes_R \mathcal{F}$  where  $\mathcal{F} = FR$ .

**Proof.** Let  $\theta_M : M \to \operatorname{Hom}_{\mathsf{A}}(\mathcal{F}, FM)$  be the composition

$$M \xrightarrow{\Lambda_M} \operatorname{Hom}_R(R, M) \xrightarrow{F} \operatorname{Hom}_A(\mathcal{F}, FM)$$

where  $\Lambda_M$  is the canonical isomorphism  $m \to \lambda_m$  where  $\lambda_m(r) := mr$  for all  $r \in R$ . Let

$$\Theta_M: M \otimes_R \mathcal{F} \to FM$$

be the map that corresponds to  $\theta_M$  under the adjoint isomorphism

 $\operatorname{Hom}_R(M, \operatorname{Hom}_A(\mathcal{F}, FM)) \cong \operatorname{Hom}_A(M \otimes_R \mathcal{F}, FM).$ 

<sup>&</sup>lt;sup>2</sup>It is essential that A be cocomplete for  $-\otimes_R \mathcal{F}$  to exist. For example, if  $R = \mathbb{Z}$  and A consists of finitely generated abelian groups and  $\mathcal{F} = \mathbb{Z}$ , there is no adjoint. But the hypothesis of cocompleteness is absent from [6, p.108] and parts of [1].

<sup>&</sup>lt;sup>3</sup>After we finished writing this paper we learned that a version of this result had already been proved by Brzezinski and Wisbauer [2, 39.3, p.410] under the hypothesis that the objects of A are abelian groups.

We will show that the  $\Theta_M$ s define a natural transformation, i.e., if  $f: M \to N$ is a homomorphism of right *R*-modules, then the diagram

commutes. Define  $\eta : \operatorname{Hom}_{\mathsf{A}}(\mathcal{F}, FM) \to \operatorname{Hom}_{\mathsf{A}}(\mathcal{F}, FN)$  by  $\eta(g) := Ff \circ g$ . The left and right squares in the diagram

$$\begin{array}{ccc} M & \xrightarrow{\Lambda_M} \operatorname{Hom}_R(R, M) & \xrightarrow{F} \operatorname{Hom}_{\mathsf{A}}(\mathcal{F}, FM) \\ f & & & & & & \\ f & & & & & \\ N & \xrightarrow{\Lambda_N} \operatorname{Hom}_R(R, N) & \xrightarrow{F} \operatorname{Hom}_{\mathsf{A}}(\mathcal{F}, FN) \end{array}$$

commute, so  $\eta \circ \theta_M = \theta_N \circ f$ . We now consider the diagram

$$\begin{array}{c} \operatorname{Hom}(M,\operatorname{Hom}(\mathcal{F},FM)) & \overset{\sim}{\longrightarrow} \operatorname{Hom}(M \otimes \mathcal{F},FM) \\ & \downarrow & \downarrow \\ \operatorname{Hom}(M,\operatorname{Hom}(\mathcal{F},FN)) & \overset{\sim}{\longrightarrow} \operatorname{Hom}(M \otimes \mathcal{F},FN) \\ & \uparrow & \uparrow \\ \operatorname{Hom}(N,\operatorname{Hom}(\mathcal{F},FN)) & \overset{\sim}{\longrightarrow} \operatorname{Hom}(N \otimes \mathcal{F},FN), \end{array}$$

whose verticals are induced by f and whose horizontals are the adjoint isomorphism. The top and bottom rectangles of this diagram commute by the functoriality of the adjoint isomorphisms. The maps  $\theta_M$  and  $\theta_N$  belong to the top and bottom Homsets of the left-hand column and their images in  $\text{Hom}(M, \text{Hom}(\mathcal{F}, FN))$  are the same because  $\eta \circ \theta_M = \theta_N \circ f$ . It follows that the images of  $\Theta_M$  and  $\Theta_N$  in  $\text{Hom}(M \otimes \mathcal{F}, FN)$  are the same. In other words,

$$Ff \circ \Theta_M = \Theta_N \circ (f \otimes \mathcal{F})$$

which proves that (3-1) commutes and hence that the  $\Theta_M$ s define a natural transformation

$$\Theta: -\otimes_R \mathcal{F} \to F.$$

Because  $(F \circ \Lambda_R)(x) = F(\mu_x) = \rho(x)$ ,  $\theta_R : R \to \operatorname{Hom}_A(\mathcal{F}, \mathcal{F})$  is the map giving  $\mathcal{F}$  its *R*-module structure, so the corresponding map  $\Theta_R : R \otimes_R \mathcal{F} \to \mathcal{F}$  is an isomorphism. Since the functors  $- \otimes_R \mathcal{F}$  and *F* commute with direct sums,  $\Theta_M$  is an isomorphism for all free *R*-modules *M*. Since  $- \otimes_R \mathcal{F}$  and *F* are right exact it follows that  $\Theta_M$  is an isomorphism whenever *M* is the cokernel of a map between free *R*-modules. But every *R*-module is of that form so  $\Theta_M$  is an isomorphism for all *M*. Hence  $\Theta$  is an isomorphism of functors.<sup>4</sup>

Proposition 3.2 says that the functor  $\Psi$  in Theorem 3.1 is essentially surjective.

 $<sup>^4\</sup>mathrm{The}$  argument in the last part of the proof is a result of B. Mitchell. See [2, 39.1, p.409] for more details.

3.2. The proof that  $\Psi$  is fully faithful. Let  $(\mathcal{F}, \rho) \in A_R$  and let  $\mathcal{N} \in A$ . The composition

$$(3-2) \qquad \operatorname{Hom}_{\mathsf{A}}(R \otimes_{R} \mathcal{F}, \mathcal{N}) \xrightarrow{\sim} \operatorname{Hom}_{R}(R, \operatorname{Hom}_{\mathsf{A}}(\mathcal{F}, \mathcal{N})) \xrightarrow{\sim} \operatorname{Hom}_{\mathsf{A}}(\mathcal{F}, \mathcal{N}),$$

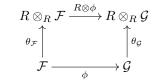

where the first map is the adjoint isomorphism and the second is the canonical isomorphism  $\psi \mapsto \psi(1)$ , induces an isomorphism of functors  $\operatorname{Hom}_{\mathsf{A}}(R \otimes_R \mathcal{F}, -) \to \operatorname{Hom}_{\mathsf{A}}(\mathcal{F}, -)$  which, by the Yoneda Lemma, corresponds to a unique isomorphism

$$\theta_{\mathcal{F}}: \mathcal{F} \longrightarrow R \otimes_R \mathcal{F}.$$

The next result is a slightly sharper form of [1, Prop. B3.1(a)].

Proposition 3.3. The diagram

(3-3)

commutes for all  $\mathcal{F}, \mathcal{G} \in A_R$  and all  $\phi \in \operatorname{Hom}_R(\mathcal{F}, \mathcal{G})$ . Therefore, the maps  $\theta_{\mathcal{F}}$  provide an isomorphism

$$\theta: \mathrm{id}_{\mathsf{A}_R} \longrightarrow (R \otimes_R -)$$

of functors.

**Proof.** By the Yoneda lemma, the commutivity of (3-3) is equivalent to the condition that for all  $\mathcal{N} \in A$  the outer rectangle in the diagram

commutes, where the vertical arrows are the factorizations in (3-2) that are used to define  $\theta_{\mathcal{F}}$  and  $\theta_{\mathcal{G}}$ , and

$$\Gamma(\psi)(x) := \psi(x) \circ \phi$$

for all  $x \in R$  and  $\psi \in \operatorname{Hom}_R(R, \operatorname{Hom}_A(\mathcal{G}, \mathcal{N}))$ .

The uppermost square of (3-4) commutes by functoriality of the adjoint isomorphism. Going clockwise around the lower square, the image in  $\operatorname{Hom}_{\mathsf{A}}(\mathcal{F}, \mathcal{N})$  of  $\psi \in \operatorname{Hom}_{R}(R, \operatorname{Hom}_{\mathsf{A}}(\mathcal{G}, \mathcal{N}))$  is  $\psi(1) \circ \phi$ . Going counter-clockwise around the lower square, the image of  $\psi$  in  $\operatorname{Hom}_{\mathsf{A}}(\mathcal{F}, \mathcal{N})$  is  $\Gamma(\psi)(1) = \psi(1) \circ \phi$ . Hence the lower square commutes.

It follows that the outer rectangle commutes.

**Lemma 3.4.** Let C be a cocomplete abelian category and let  $F, G : \operatorname{Mod} R \to C$  be right exact functors that commute with direct sums. Let  $\tau, \tau' : F \to G$  be natural transformations. If  $\tau_R = \tau'_R$ , then  $\tau = \tau'$ .

**Proof.** Let  $M_i$ ,  $i \in I$ , be a collection of right *R*-modules. Then there is a natural map

$$\bigoplus_{i\in I} FM_i \to F\left(\bigoplus_{i\in I} M_i\right)$$

and the fact that F commutes with direct sums says that this map is an isomorphism. By the universal property of colimits, there is a commutative diagram

Since the horizontal maps are isomorphisms, if  $\tau_{M_i} = \tau'_{M_i}$  for all *i*, then

$$\tau_{\oplus M_i} = \tau'_{\oplus M_i}.$$

In particular, it follows that  $\tau_P = \tau'_P$  for all free *R*-modules *P*.

Let M be a right R-module and let  $P \to Q \to M \to 0$  be an exact sequence in which P and Q are free R-modules. Then there is a commutative diagram

$$\begin{array}{c} FP \longrightarrow FQ \longrightarrow FM \longrightarrow 0 \\ \tau_P \downarrow & \tau_Q \downarrow \\ GP \longrightarrow GQ \longrightarrow GM \longrightarrow 0, \end{array}$$

and a unique map  $FM \to GM$  making the diagram commute, namely  $\tau_M$ . Since  $\tau_P = \tau'_P$  and  $\tau_Q = \tau'_Q$ , it follows that  $\tau_M = \tau'_M$ .

Now we prove that  $\Psi$  is fully faithful. Let  $\mathcal{F}$  and  $\mathcal{G}$  be objects in  $A_R$  and let  $\phi \in \operatorname{Hom}_R(\mathcal{F}, \mathcal{G})$ . By Proposition 3.3, the diagram

$$(3-5) \qquad \qquad R \otimes_R \mathcal{F} \xrightarrow{R \otimes \phi} R \otimes_R \mathcal{G}$$
$$\theta_{\mathcal{F}} \uparrow \qquad \qquad \uparrow \\ \mathcal{F} \xrightarrow{\varphi} \mathcal{G}$$

commutes. It follows from this that  $R\otimes\phi$  is non-zero if  $\phi$  is non-zero. Hence  $\Psi$  is faithful.

To complete the proof of Theorem 3.1, it remains to show that  $\Psi$  is full. To that end, let

$$\tau:-\otimes_R \mathcal{F}\to -\otimes_R \mathcal{G}$$

be a natural transformation. We must show there is a homomorphism  $\phi \in \operatorname{Hom}_R(\mathcal{F}, \mathcal{G})$ such that  $\tau_M = M \otimes \phi$  for all  $M \in \operatorname{Mod} R$ .

Define

$$\phi := \theta_C^{-1} \circ \tau_R \circ \theta_{\mathcal{F}}$$

It follows from the commutativity of (3-5) that  $R \otimes \phi = \tau_R$ . By Lemma 3.4, it follows that  $M \otimes \phi = \tau_M$  for all  $M \in \mathsf{Mod}R$ . In other words,  $\Psi(\phi) = \tau$ .

## A. NYMAN AND S. P. SMITH

#### 4. An Application

Throughout this section, let X denote a k-scheme. If  $X = \operatorname{Spec} R$ , we let

 $(-): \mathsf{Mod}R \to \mathsf{Qcoh}X$ 

be the quasi-inverse to the global sections functor defined in [4, II, Definition, p. 110].

**Example 4.1.** Let  $f: Y \to X$  be a morphism from an arbitrary scheme to an affine scheme  $X = \operatorname{Spec} R$ . Then  $f^* \circ (-) : \operatorname{\mathsf{Mod}} R \to \operatorname{\mathsf{Qcoh}} Y$  is a right exact functor commuting with direct sums. Proposition 3.2 says that  $f^* \circ (-) \cong - \otimes_R \mathcal{O}_Y$  where  $\mathcal{O}_Y$  is made into an *R*-module via the ring homomorphism

$$R \to \operatorname{Hom}_R(R, R) \to \operatorname{Hom}_Y(f^*\mathcal{O}_X, f^*\mathcal{O}_X) \to \operatorname{Hom}_Y(\mathcal{O}_Y, \mathcal{O}_Y)$$

where the first map sends  $r \in R$  to multiplication by r, the second map is induced by  $f^* \circ (-)$  and the third isomorphism is induced by the natural isomorphism  $f^*\mathcal{O}_X \cong \mathcal{O}_Y$ .

The motivation for this paper lies in the paper [5], in which k-schemes X and Y and k-linear functors  $F : \operatorname{Qcoh} X \to \operatorname{Qcoh} Y$  that are right exact and commute with direct sums are considered. One source of such functors is the following. Let  $\mathcal{F}$  be a quasi-coherent sheaf on  $X \times_k Y$ , and define

(4-1) 
$$- \otimes_{\mathcal{O}_X} \mathcal{F} := \operatorname{pr}_{2*}(\operatorname{pr}_1^*(-) \otimes_{\mathcal{O}_{X \times_k Y}} \mathcal{F})$$

where  $\operatorname{pr}_i : X \times_k Y \to X, Y, i = 1, 2$ , are the obvious projections. A functor of the form  $- \otimes_{\mathcal{O}_X} \mathcal{F}$  is not always an object of  $\mathsf{B}_k(\mathsf{Qcoh}X,\mathsf{Qcoh}Y)$ . This happens, for example, if  $Y = \operatorname{Spec} k, X = \mathbb{P}^1_k$  and  $F = - \otimes_{\mathcal{O}_X} \mathcal{O}_{X \times Y} \cong \Gamma(X, -)$ .

On the other hand, an object of  $\mathsf{B}_k(\mathsf{Qcoh}X,\mathsf{Qcoh}Y)$  is not always isomorphic to one of the form  $-\otimes_{\mathcal{O}_X} \mathcal{F}$ . This happens, for example, if  $Y = \operatorname{Spec} k$ ,  $X = \mathbb{P}^1_k$  and  $F = H^1(X, -)$  [5, Proposition 5.4].

The question motivating [5] is whether F is isomorphic to a functor of the form  $- \otimes_{\mathcal{O}_X} \mathcal{F}$ . It follows from Theorem 3.1 that this is always the case if X is affine, as we now show.

**Proposition 4.2.** Let R be a k-algebra and Y a k-scheme. Write  $X := \operatorname{Spec} R$ . Then the inclusion functor

$$\mathsf{Qcoh}(X \times_k Y) \to \mathsf{B}_k(\mathsf{Qcoh}X,\mathsf{Qcoh}Y), \qquad \mathcal{F} \mapsto - \otimes_{\mathcal{O}_X} \mathcal{F},$$

is an equivalence of categories.

**Proof.** By [4, II, exercise 5.17e], the functor

 $\operatorname{pr}_{2*}: \operatorname{\mathsf{Qcoh}}(X \times_k Y) \to \operatorname{\mathsf{Qcoh}}(\operatorname{pr}_{2*} \mathcal{O}_{X \times_k Y})$ 

is an equivalence, where  $\mathsf{Qcoh}(\mathrm{pr}_{2*}\mathcal{O}_{X\times_k Y})$  denotes the category of quasi-coherent  $\mathcal{O}_Y$ -modules with  $\mathrm{pr}_{2*}\mathcal{O}_{X\times_k Y}$ -module structure. Furthermore, it is straightforward to check that the functor

$$\operatorname{\mathsf{Qcoh}}(\operatorname{pr}_{2*}\mathcal{O}_{X\times_k Y}) \to (\operatorname{\mathsf{Qcoh}} Y)_R$$

induced by the assignment  $\mathcal{E} \mapsto (\mathcal{E}, \rho)$ , where  $\rho : R \to \operatorname{Hom}_Y(\mathcal{E}, \mathcal{E})$  is defined through the  $\operatorname{pr}_{2*} \mathcal{O}_{X \times_k Y}$ -structure of  $\mathcal{E}$ , is an equivalence. By Theorem 3.1, the functor

$$(\mathsf{Qcoh}Y)_R \to \mathsf{B}_k(\mathsf{Mod}R,\mathsf{Qcoh}Y)$$

8

induced by the assignment  $(\mathcal{E}, \rho) \mapsto - \otimes_R \mathcal{E}$  is an equivalence. Therefore, the functor

 $\mathsf{Qcoh}(X \times_k Y) \to \mathsf{B}_k(\mathsf{Mod}R,\mathsf{Qcoh}Y)$ 

induced by the assignment  $\mathcal{F} \mapsto - \otimes_R \operatorname{pr}_{2*} \mathcal{F}$  is an equivalence. By the uniqueness properties of the functor  $- \otimes_R \mathcal{E}$  described in Section 2.4, we have an isomorphism of functors

$$-\otimes_R \operatorname{pr}_{2*} \mathcal{F} \xrightarrow{\sim} \widetilde{(-)} \otimes_{\mathcal{O}_X} \mathcal{F}$$

in  $B_k(R, QcohY)$ . It follows that the functor

$$\operatorname{\mathsf{Qcoh}}(X \times_k Y) \to \mathsf{B}_k(\operatorname{\mathsf{Mod}} R, \operatorname{\mathsf{Qcoh}} Y)$$

induced by the assignment  $\mathcal{F} \mapsto (\widetilde{(-)} \otimes_{\mathcal{O}_X} \mathcal{F}$  is an equivalence. The claim follows easily from this.  $\Box$
